

Dive 79 - Little Brother Island - 15-04-2013

Little Brother Island is shaped like a rain drop, falling from the north west to south east. Deep walls surround the island on all sides except the northern point, where the reef slopes very slowly away from the island before dropping to a deep plateau at 40m.

On the eastern and western walls, it's not about size but about quality. Surrounded by sheer walls covered with black corals, mammoth gorgonian fans with exceptionally dense hard and soft corals covering the spectrum of colours, it's easy to

miss all the beauty as your view is obscured by schools of fish so plentiful that it often blocks out the light.

The current on both these walls tends to run from north to south, so you are likely to end a dive on either wall at the southern plateau. This is a wide ledge some 20m or more deep.
